## GENERAL DESCRIPTION

The microprocessor camera control system consists of a Master Control Panel, Remote Control Panels, and Control Receivers. The receivers are packaged in NEMA-4 weatherproof enclosures. These units can be arranged to meet the needs of virtually any CCTV control application.

The system transmits control signals over either a single twisted pair (RS-485) or dual twisted pair (RS-422). DTMF is available as an option. Control receivers are compatible with existing systems that use these transmission formats.

A design offering many optional features allows a system to be assembled from off-the-shelf components to meet the specific needs of nearly any application.

The system controls up to 223 cameras and, if required, pan/tilt units. Up to 31 remote control sites and 1 master can be employed in the system.

Up to 10 preset positions for each camera/lens, and pan/tilt unit are available as an option. These positions are programmed and selected using the Preset Control Unit.

Receivers and remote control panels may be located up to 8 km (5 miles) from each other in a daisy-chain arrangement, using Belden 9182 twisted-pair wire. By using an MPC RS-422 Distribution Unit, the receivers may also be hooked in a star pattern, with each point of the star having up to 31 receivers.

Receivers obtain data from the Master Control Panel. This data is decoded to generate all drive signals for the pan/tilt, camera, and lens. If the preset option is used, the preset positions are stored in non-volatile RAM to prevent loss of memory during power interruptions.

The receiver processes the commands, then responds appropriately via the serial link and performs necessary control functions to the camera, lens, and pan/tilt unit. The receiver enclosure has multi-pin MS-type connectors for interconnecting with the camera and pan/tilt unit. In addition to normal camera site functions (pan, tilt, zoom, focus, iris, camera power, lens speed), other functions can be performed. These optional functions include contact closure, logic level input/output, ac/dc drive voltages, or dc analog voltage output or measurement. The receiver board jumper table details the configurations available for these functions.

## INSTALLATION

Control receiver installation consists of installing the receiver at the desired location, setting an internal address, and connecting cables. Use four bolts, one at each corner, to secure the receiver. If units are to be daisy-chained together, use the wiring arrangement shown in the figure for the plug that interconnects with the receiver. Note that the last unit in the chain must be terminated with a 1/4 watt resistor with a value between 150 and 600 ohms. Daisy-chained refers to a method of connection that passes the control signals from unit to unit in a series arrangement (see figure). A wire-pair (or two pairs) enters the receiver and then exits again through the same connector to the next receiver in the chain.

The equipment may also be interconnected using a star arrangement, where each unit receives its own data line from a distribution unit (see figure).

Each receiver must have a unique address. This address is established by an 8-pole DIP switch on the receiver board. These switch settings are read by the microcomputer only when power is applied. If an address is changed while the receiver is powered up, be sure to power down and back up again to read in the new address.

To set the address, remove the cover by loosening the eight clamp screws securing the cover. Slide the clamps off of the cover and remove it. Switch S1 is located at the top of the receiver board. Refer to the receiver board adjustments and jumpers figure and the decimal-hex-binary conversion table to determine the desired setting.

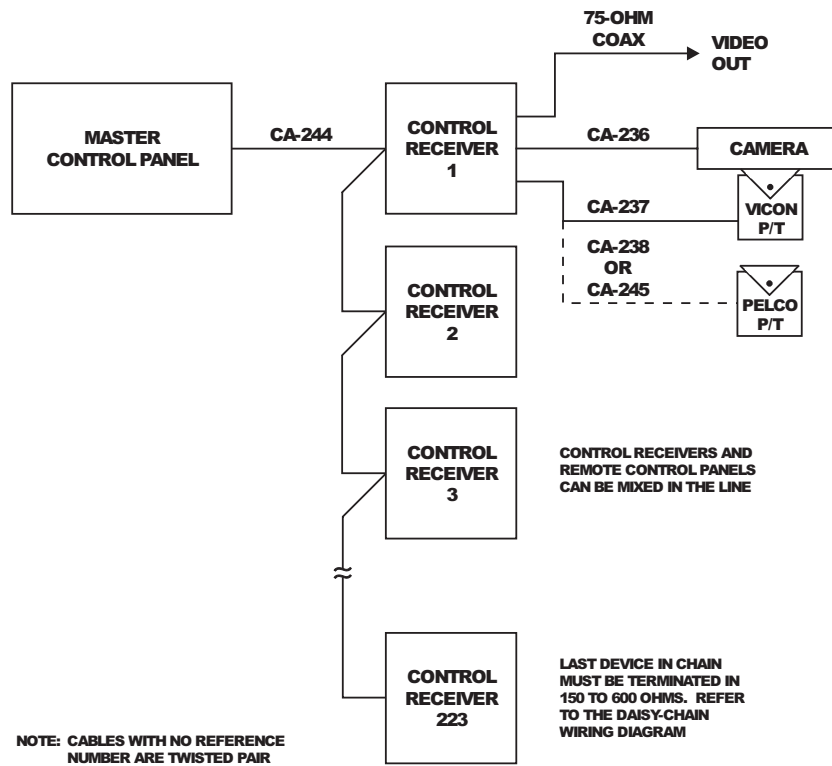

Replace the cover and slide the clamps back into position. Install the eight screws and tighten a little at a time in an alternating cross-pattern to evenly pull the cover down onto the gasket. This ensures that the receiver enclosure is properly sealed. Make sure that all cable connections are made to the receiver before applying power.

## OPERATION

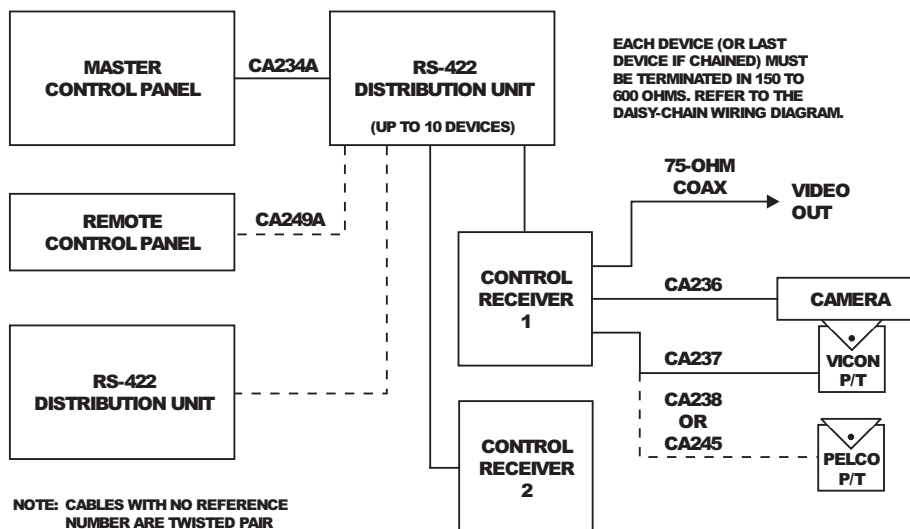

All operating characteristics of the receiver are controlled by an MPC Master or Remote Control Panel. Refer to the control panel manual for operating instructions.

# AC PAN/TILT BOARD (9084-8)

## GENERAL DESCRIPTION

The AC Pan/Tilt board allows an MPC Receiver to control an ac-powered pan/tilt unit. The board is supplied with the necessary connectors and cables for installation into an MPC receiver. The standard version of the board controls a 115-VAC pan/tilt unit. An optional transformer is available to allow the board to control a 230-VAC unit.

## INSTALLATION

### CAUTION

**Remove power from the MPC receiver before removing the cover.**

To install the board in an MPC receiver, remove the cover by loosening the eight clamp screws securing the cover. Slide the clamps off of the cover and remove it.

Locate connectors P21 through P24 and plug into connectors J21 through J24 on the board (J25 and J26 are not used). Note that the connectors are keyed.

The chamfered end of the board slides into the guide on the side of the receiver card cage opposite the main I/O connectors. The bottom cutout on the opposite end of the board fits into the cutout on the bottom of the card cage. The board is held in place by the receiver housing lid. Ensure that the connector wiring is routed correctly to prevent them from being pinched underneath the board.

Check that the NORMAL/AUTO jumper is in the NORMAL position, and that the A/B/C jumper is in the A/B position.

Replace the cover and slide the clamps back into position. Install the eight screws and tighten a little at a time in an alternating cross-pattern to evenly pull the cover down onto the gasket. This ensures that the receiver enclosure is properly sealed. Make sure that all cable connections are made to the receiver before applying power.

## OPERATION

All operating functions of the ac pan/tilt board are controlled from an MPC Master or Remote Control Panel. Refer to the control panel manual for operating instructions.

Connector and Jumper Locations, AC Pan/Tilt Board

# DC PAN/TILT BOARD (9098-9)

## GENERAL DESCRIPTION

The DC Pan/Tilt board allows an MPC Receiver to control a 115-VDC pan/tilt unit.

## INSTALLATION

### CAUTION

**Remove power from the MPC receiver before removing the cover.**

A DVM will be necessary to set the dc output pan and tilt voltages.

To install the board in an MPC receiver, remove the cover by loosening the eight clamp screws securing the cover. Slide the clamps off of the cover and remove it.

Locate connectors P21 through P24 and plug into connectors J21 through J24 on the board (J25, J48, and J50 are not used). Note that the connectors are keyed.

The chamfered end of the board slides into the guide on the side of the receiver card cage opposite the main I/O connectors. The bottom cutout on the opposite end of the board fits into the cutout on the bottom of the card cage. The board is held in place

by the receiver housing lid. Ensure that the connector wiring is routed correctly to prevent them from being pinched underneath the board.

Connect the DVM to J21-2 and -6. Apply power to the receiver and activate the TILT UP function from the control panel and set R29 (TILT SPEED) for 115 VDC. Repeat for J21-5 and -6, PAN RIGHT, and R26 (PAN SPEED). Remove power from the receiver.

Replace the cover and slide the clamps back into position. Install the eight screws and tighten a little at a time in an alternating cross-pattern to evenly pull the cover down onto the gasket. This ensures that the receiver enclosure is properly sealed. Make sure that all cable connections are made to the receiver before applying power.

## OPERATION

All operating functions of the dc pan/tilt board are controlled from an MPC Master or Remote Control Panel. Refer to the control panel manual for operating instructions.

Connector and Jumper Locations, DC Pan/Tilt Board
